Material and Methods

Study areas

Herbivorous insects were studied in two temperate areas, Moravia and Slovakia in Central Europe, and one tropical area, Madang in Papua New Guinea. The Moravia study area in the Poodri Protected Area ($18^{\circ}03\text{--}13'\text{E}$, $49^{\circ}42\text{--}48'\text{N}$, 200 m asl., Czech Republic) included three fragments of the primary floodplain forest (Rezavka, Polansky Les and Polanska Niva Natural Reserves, 300 ha in total) along a 20 km long section of the Odra River. The forest vegetation was dominated by *Quercus*, *Ulmus*, *Tilia*, *Prunus* and *Fraxinus*. The annual average temperature was $7\text{--}8.5^{\circ}\text{C}$, the annual average rainfall 600–800 mm (S1).

The Slovakia study area of 120×80 km between the Borska nizina Lowland and Hronska pahorkatina Hills ($16^{\circ}58'\text{--}18^{\circ}38'\text{E}$, $47^{\circ}34\text{--}48'\text{N}$, 100–350 m asl., Slovak Republic) included 15 study sites with lowland thermophilous oak and oak-hornbeam forests. The annual average temperature was $7\text{--}10^{\circ}\text{C}$, the annual average rainfall 550–900 mm (S1).

The Papua New Guinea study area in Madang Province ($145^{\circ}41\text{--}8'\text{E}$, $5^{\circ}08\text{--}14'\text{S}$, 0–200 m asl.) included three study sites (Baitabag, Ohu, and Mis Villages) within a 10×20 km area, encompassing a mosaic of secondary and primary lowland hill forest. The annual average temperature was 26.5°C , and the annual average rainfall 3,600 mm (S2).

Estimates of woody plant species richness per hectare in tropical and temperate forests were based on total enumeration of woody stems ≥ 10 cm in diameter at breast height (DBH) in one hectare plots. Published estimates from 36 tropical forest plots were assembled from the three major tropical regions (S3–S7). Eighteen temperate forest plots were drawn from the eastern deciduous forests of North America, which are among the most diverse temperate forests known (S3, S5, S8), and New Zealand (S9).

Study plants

In Moravia, we studied 14 locally common woody species, including both closely and distantly related species. The study species represented $85 \pm 2.4\%$ of the total forest basal area according to 62 plots $25 \text{ m} \times 25 \text{ m}$ each, or 3.75 ha in total, where all plants $\geq 5\text{cm}$ in diameter at breast height (DBH) were recorded. In Slovakia, eight woody species were studied.

In Papua New Guinea, we used a phylogeny estimate for 60 locally common woody species (S10) to select subsets of species with phylogenetic structure matching that of the Moravia and Slovakia study trees. Subsets matching Moravia included $19 \pm 2.2\%$ of the total basal area in the local New Guinea forest, estimated from 100 plots $20 \text{ m} \times 20 \text{ m}$, or four ha in total, where all plants $\geq 5\text{cm}$ in DBH were recorded. The subset matching Slovakia included $9 \pm 1.4\%$ of the local basal area in New Guinea.

Community phylogeny

A phylogeny estimate for each temperate and tropical tree community sample was obtained by grafting less inclusive single-gene phylogenetic hypotheses into a more inclusive phylogeny of angiosperms based on three genes (S11) as described in (S10). Additional phylogenetic information was drawn from (S12–S14). The assembly of a community phylogeny can follow supertree methods (S15) but one crucial difference is that only members of the community are retained in the supertree while all other lineages are pruned away.

Phylogenetic branch lengths are also important to consideration for community samples. When branch lengths are assumed equal, using the number of intervening nodes as a proxy for phylogenetic

distance, relationships between intensively sampled congeneric species are given the same weight as relationships among representatives of major clades. Branch length information can distinguish between these two very different cases, short distances between congeners and long distances between members of major lineages. Branch lengths for community phylogenies of temperate trees were approximated from aligned DNA sequences encoding ribulose-1,5-bisphosphate carboxylase (*rbcL*). Sequences 1,380 base pairs in length were obtained from Genbank for each tree species and the closest available relative was substituted as indicated in Table S1 when particular taxa were not available. Branch lengths were optimized on each community phylogeny under parsimony using PAUP* (S16).

The same approach was applied to estimate phylogenetic branch lengths for tropical tree community samples, except that there were an insufficient number of *rbcL* sequences in Genbank for *Ficus* and Euphorbiaceae. Branch lengths were estimated for *Ficus* from the internal transcribed spacer region of nuclear ribosomal DNA (ITS) and for Euphorbiaceae from the *ndhF* gene encoding a subunit of NADH-plastoquinone oxidoreductase. ITS and *ndhF* branch lengths were scaled to the relative rate of change in *rbcL* compared between pairs of taxa. For example, the relative rate of ITS to *rbcL* was calculated by counting the absolute number of character differences in each gene between *Ficus heterophylla* and *F. pumila*. *rbcL* sequences for *F. heterophylla* (AF500351) and *F. pumila* (AF500352) differed by 12 substitutions compared to 36 substitutions in ITS, yielding a rate of 0.30 by which ITS branch lengths were multiplied to express them in *rbcL* units on the community phylogeny. The rate used for *ndhF* relative to *rbcL* was 0.52 as described in (S10). We rescaled the branch lengths by these rates to approximate the phylogenetic distance between taxa sampled for genes with different rates of molecular divergence.

Next we obtained a community phylogeny for which all distances from the root of the tree to the tips are equal, also known as an ultrametric tree. Ultrametricity is necessary to make direct comparisons of phylogenetic distance (as measured by rescaled molecular branch lengths) among pairs of host species distributed across the phylogeny. Each individual molecular dataset rejected a molecular clock assumption, so we applied nonparametric rate smoothing (S17) as implemented in the program TreeEdit (S18). Ultrametric distances between ancestral and descendant nodes from temperate and tropical community phylogenies were compared using TreeMap software (S19).

Insect sampling

In Moravia, all externally feeding folivorous insects were hand collected from the foliage of 14 tree species throughout the growing seasons during 1999-2001. Sampling effort amounted to 150 m² of foliage inspected per tree species. All 14 tree species were sampled at each of the three study forests.

In Slovakia, all externally feeding caterpillars (Lepidoptera) were sampled from 450 m² of foliage inspected per tree species. For each tree species, 25 m² of foliage were sampled on six days throughout the growing season. Each species was sampled during three growing seasons, either at three different sites, or at two sites with one site sampled in two different years. Sampling included 15 different sites and extended from 1978 to 2002 as described in detail previously (S20-S22).

In Papua New Guinea, all externally feeding folivorous insects were hand collected from the foliage of 14 tree species. Each tree species was sampled for at least one year between 1994-2000. The sampling effort amounted to 1,500 m² of foliage per tree species. All 14 tree species were sampled at each of the three study sites as described in (S23).

Laboratory rearing procedures were identical for all three study areas. Each insect was provided with fresh leaves of the plant species from which it was collected and only those that fed were retained in the analyses. Larvae were identified to morphospecies and/or reared to adults. All insects assigned to morphospecies were later verified and identified by taxonomic specialists. Taxonomic methods for

Papua New Guinea material are detailed in (S23). Vouchers are deposited at the University of Ostrava, Ostrava (Moravia specimens), Comenius University, Bratislava (Slovakia specimens) and the National Agricultural Research Institute of Papua New Guinea, Bishop Museum, Honolulu and Smithsonian Institution, Washington (Papua New Guinea specimens).

Predation pressure on the foliage of the studied trees was assessed as the proportion of live baits, represented by *Calliphora vicina* fly larvae in Moravia and *Microcerotermes biroi* termite workers in Papua New Guinea, that were attacked by predators during 30 minutes of exposure on the foliage (S24). Twenty experiments, each including 30 baits exposed on a single tree, were conducted on each study tree species in Moravia and Papua New Guinea (Table S2).

Data analysis

Only feeding insects and host plant records supported by more than one feeding observation were included in the analysis in order to exclude tourists and marginal feeders. The number of species per 100 m² of foliage was interpolated from the entire sample obtained for each tree species by rarefaction.

Host specificity was measured as the number of study species used as hosts by a particular herbivorous species. This simple count of host species was appropriate given a nearly identical phylogenetic distribution of temperate and tropical study plants.

Community similarity was assessed by the Chao-Sorensen index, a modification of the classical Sorensen index that corrects its bias due to incomplete sampling of communities, calculated by EstimateS (S25). The similarity of herbivore communities was correlated with the phylogenetic distance of their host plants, for all pair-wise comparisons between the studied plant species.

Phylogenetic distance was estimated as the absolute number of substitutions between pairs of species in the ultrametric tree using TreeEdit (S18). The significance of the correlation between herbivore community similarity and host phylogenetic distance was evaluated with the Mantel test.

The differences in species richness and density of herbivores between temperate and tropical trees were tested by t-test. Further, comparative analyses incorporating phylogenetic relationships of host plants were also performed because tropical and temperate tree species are not statistically independent. For the Moravia-New Guinea and Slovakia-New Guinea comparisons of species richness and abundance, supertrees combining temperate and tropical taxa were assembled. Molecular branch lengths were estimated and rate-smoothed under parsimony as described above. Phylogenetic generalized least squares (PGLS) regression analysis was performed using the program COMPARE (S26) with temperate versus tropical as a categorical predictor variable and herbivore species richness or abundance per host species as the response variable. The standard error of the regression slope was used to test the significance of differences between tropical and temperate herbivore communities as described in (S26).

Corrected 25 August 2006

On page 2, in the second paragraph under “Study areas,” “oak-hawthorn” has been changed to “oak-hornbeam.”

On page 5, reference S10 has been updated to include the volume and page numbers.

Tables, Figures and Appendices

Table S1. Woody plant species sampled for insect herbivores in temperate and tropical forests. Major clades, orders and families follow the Angiosperm Phylogeny Group classification (S27). DNA sequences retrieved from Genbank were used to estimate branch lengths on a community phylogeny for the set of tree species sampled at each study site. When DNA sequences were unavailable for a particular species, a sequence from a related species was substituted for the purpose of branch length estimation.

<i>Acer campestre</i>	1.2	<i>Pometia pinnata</i>	40.5
Average	1.6	Average	28.3

Figure S1. The relationship between latitude and species richness of woody plants ≥ 10 cm DBH from 58 one-hectare plots worldwide, including our two study areas (S28, S4-S9, P. J. Bellingham, pers. comm, and references in S3). Woody plant species richness declined significantly with increasing latitude ($R^2 = 0.624$).

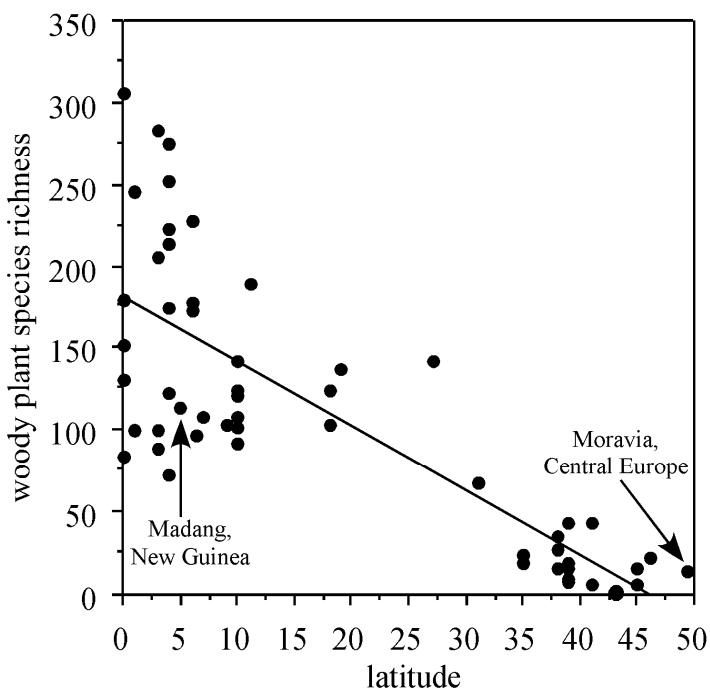

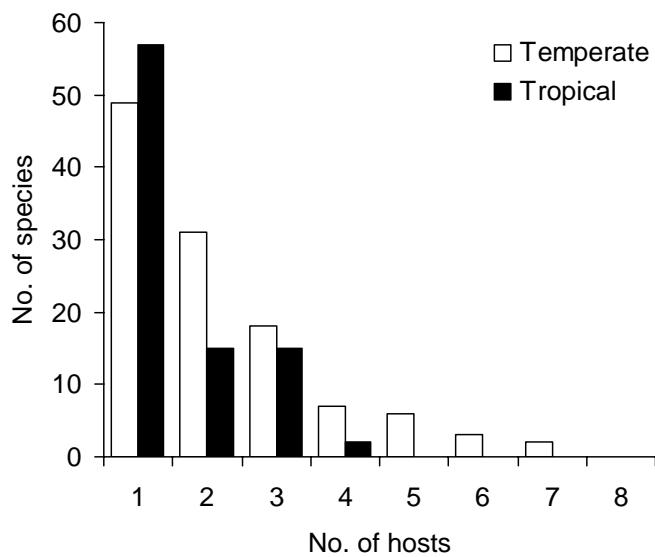

Figure S2. Host specificity of Lepidoptera on temperate and tropical trees. The number of hosts among eight study species of trees (Fig. 1C) is shown for Slovakia and New Guinea. The median host range of two temperate tree species per herbivore species was significantly different from the median host range of a single tropical tree species per herbivore (Mann-Whitney test, $P < 0.001$).

Appendix S1. Taxonomy and abundance of herbivore species from Central Europe (Moravia and Slovakia). Morphospecies with unknown adult stages are marked with an asterisk. Morphospecies codes are used for unidentified species. Note that only Lepidoptera were studied in Slovakia.

Coleoptera	Throscidae	<i>Drapetes</i> cf. <i>argenteopilosus</i>	1
Orthoptera	Acrididae	<i>Gesonula mundata</i> Walker	17

Appendix 2 Continuing

Order	Family	Species	N
Orthoptera	Acrididae	<i>Oxya japonica vitticollis</i> (Blanchard)	12
Orthoptera	Acrididae	<i>Rectitropis brunneri</i> Bolivar	36
Orthoptera	Acrididae	<i>Stenocatantops angustifrons</i> (Walker)	27
Orthoptera	Acrididae	<i>Valanga papuasica</i> Finot	109
Orthoptera	Acrididae	<i>Willemsea bimaculata</i> Willemse	3
Orthoptera	Eumastacidae	<i>Biroella bolivari polita</i> (Bolivar)	30
Orthoptera	Eumastacidae	<i>Mnesiclesina furcata</i> (Saussure)	22
Orthoptera	Eumastacidae	<i>Paramnesicles buergersi</i> (Bolivar)	38
Orthoptera	Pyrgomorphidae	<i>Atractomorpha crenaticeps</i> Blanchard	158
Orthoptera	Pyrgomorphidae	<i>Desmopterella biroi</i> (Bolivar)	648
Orthoptera	Pyrgomorphidae	<i>Menesesia novaeguineae</i> Willemse	34
Orthoptera	Pyrgomorphidae	<i>Stenoxyphus aurantiacus</i> (Karsch)	26
Orthoptera	Pyrgomorphidae	Unidentified [PYRG010]	1
Orthoptera	Tettigoniidae	<i>Aphroptera biroi</i> Bolivar	3
Orthoptera	Tettigoniidae	<i>Aucaloplacella</i> sp. [TETT011]	2
Orthoptera	Tettigoniidae	<i>Aucaloplacella</i> sp. [TETT061]	13
Orthoptera	Tettigoniidae	<i>Biroa</i> sp. [TETT041]	1
Orthoptera	Tettigoniidae	<i>Caedicia</i> sp. [TETT049]	5
Orthoptera	Tettigoniidae	<i>Caedicia</i> sp. [TETT034]	3
Orthoptera	Tettigoniidae	<i>Caedicia</i> sp. [TETT053]	1
Orthoptera	Tettigoniidae	<i>Conocephalus semivittatus</i> (Walker)	1
Orthoptera	Tettigoniidae	<i>Ducetia</i> sp. [TETT036]	4
Orthoptera	Tettigoniidae	<i>Eumecopoda cyrtoscelis</i> (Karsch)	4
Orthoptera	Tettigoniidae	<i>Eumecopoda</i> sp. [TETT019]	3
Orthoptera	Tettigoniidae	<i>Nicsara</i> cf. <i>taylori</i> Hebard	2
Orthoptera	Tettigoniidae	<i>Paradiaphlebus</i> sp. [TETT030]	1
Orthoptera	Tettigoniidae	<i>Phaneroptera</i> sp. [TETT023]	15
Orthoptera	Tettigoniidae	<i>Phrictaenypus</i> sp. [TETT009]	2
Orthoptera	Tettigoniidae	<i>Phyllophora</i> cf. <i>bispinosa</i> Karny	5
Orthoptera	Tettigoniidae	<i>Phyllophora</i> sp. [TETT001]	9
Orthoptera	Tettigoniidae	<i>Phyllophora</i> sp. [TETT012]	7
Orthoptera	Tettigoniidae	<i>Phyllophorella</i> sp. [TETT010]	4
Orthoptera	Tettigoniidae	<i>Pseudononcsara aerugifrons</i> (Karny)	1
Orthoptera	Tettigoniidae	<i>Psyrana</i> sp. [TETT043]	3
Orthoptera	Tettigoniidae	<i>Psyrana</i> sp. [TETT048]	3
Orthoptera	Tettigoniidae	<i>Psyrana</i> sp. [TETT022]	143
Orthoptera	Tettigoniidae	<i>Sasima aequalis</i> Karny	9
Orthoptera	Tettigoniidae	<i>Sasima</i> sp. [TETT037]	2
Orthoptera	Tettigoniidae	<i>Segestidea</i> sp. [TETT031]	2
Orthoptera	Tettigoniidae	<i>Tympanoptera</i> cf. <i>burgersi</i> Beier	27
Orthoptera	Tettigoniidae	<i>Tympanoptera</i> sp. [TETT027]	4
Orthoptera	Tettigoniidae	Unidentified [TETT044]	21
Orthoptera	Tettigoniidae	Unidentified [TETT045]	18
Orthoptera	Tettigoniidae	Unidentified [TETT002]	11
Orthoptera	Tettigoniidae	Unidentified [TETT038]	11
Orthoptera	Tettigoniidae	Unidentified [TETT006]	8
Orthoptera	Tettigoniidae	Unidentified [TETT035]	8
Orthoptera	Tettigoniidae	Unidentified [TETT018]	5
Orthoptera	Tettigoniidae	Unidentified [TETT062]	5
Orthoptera	Tettigoniidae	Unidentified [TETT042]	3
Orthoptera	Tettigoniidae	Unidentified [TETT052]	3
Orthoptera	Tettigoniidae	Unidentified [TETT040]	2
Orthoptera	Tettigoniidae	Unidentified [TETT054]	2
Orthoptera	Tettigoniidae	Unidentified [TETT014]	1
